### P-WAVE CHARM MESONS AS A WINDOW TO THE $D_{sJ}$ STATES\*

#### STEPHEN GODFREY

Ottawa-Carleton Institute for Physics, Department of Physics, Carleton University, Ottawa, Canada K1S 5B6

In my talk I discussed the properties of the newly discovered  $D_{sJ}^*(2317)$ ,  $D_{sJ}(2460)$ , X(3872), and SELEX  $D_{sJ}^*(2632)$  states and suggested experimental measurements that can shed light on them. In this writeup I concentrate on an important facet of understanding the  $D_{sJ}$  states, the properties of the closely related  $D_0^*$  and  $D_1'$  states. These states are well described as the broad, j=1/2 non-strange charmed P-wave mesons.

Keywords: Charm Mesons; Charm-strange mesons; quark model.

#### 1. Introduction

The last sixteen months has seen the discovery of the  $D_{sJ}^*(2317)^1$ ,  $D_{sJ}(2460)^2$ ,  $X(3872)^3$ , and  $D_{sj}(2632)^4$  states. All of these states have properties significantly different from what was predicted beforehand for conventional  $q\bar{q}$  states. This has led to considerable theoretical speculation that these states may be something new such as multiquark states or meson-molecules. Another point of view is that conventional  $q\bar{q}$  explanations cannot yet be ruled out and there are diagnostic tests that should be applied to understand the nature of these newly discovered states. In my talk I discussed the  $q\bar{q}$  possibilities for these new states and the quark model predictions that can be used to test them. Due to length restrictions I will restrict this writeup to new results on the  $D_0^*$ ,  $D_1'$ , and  $D_{sJ}$  states and refer the interested reader to published work on the  $X(3872)^5$  and SELEX  $D_{sJ}^+(2632)^6$  states.

## 2. The $D_{sJ}$ States and Their Nonstrange Partners

The four L=1 P-wave mesons can be grouped into two doublets characterized by the angular momentum of the light quark: j=3/2, 1/2. The j=3/2  $c\bar{s}$  states were predicted to be relatively narrow and are identified with the  $D_{s1}(2536)$  and  $D_{s2}(2573)$  states while the  $D_{s0}^*$  and  $D_{s1}' j=1/2$  states were expected to have large S-wave widths decaying to DK and  $D^*K$  respectively<sup>7</sup>. Quite unexpectedly the Babar<sup>1</sup> and CLEO<sup>2</sup> collaborations discovered two charm-strange mesons in B-decay, decaying to  $D_s^+\pi^0$  and  $D_s^{*+}\pi^0$  which were below the DK and  $D^*K$  threshold respectively. Virtually all the theoretical effort has concentrated on these states <sup>8</sup>.

However, their nonstrange partners can also hold important clues to the puzzle but have received almost no attention.

The measured properties of the L=1 charmed mesons are summarized in Table 1 along with quark model predictions  $^{7,9,10}$ . The quark model gives a P-wave cog that is  $\sim 40$  MeV too high but the splittings are in very good agreement with the measured masses. The width predictions are given for the pseudoscalar emission model with the flux-tube model giving qualitatively similar results  $^7$ . We note that Belle  $^{11}$  and FOCUS  $^{12}$  measure  $\Gamma(D_2^{*0})=37\pm4.0$  MeV and  $\Gamma(D_1^0)=23.7\pm4.8$  MeV which are slightly larger than the PDG values. They attribute the difference from older results to taking into account interference with the broader D states. Overall the agreement between theory and experiment is quite good.

Table 1. Comparison of Quark Model Predictions<sup>7,9,10</sup> to Experiment for the L=1 Charm Mesons.

State	Mas	s (MeV)	Width (MeV)		
	Theory <sup><math>a</math></sup>	Expt	Theory $^{b,7,10}$	Expt	
$D_2^*$	2460	$2459 \pm 2$ $^c$	54	$23 \pm 5$ $^c$	
$\overline{D_1}$	2418	$2422\pm1.8$ $^c$	24	$18.9^{+4.6}_{-3.5}$ c	
$D_1'$	2428	$2438 \pm 30^{-d}$	250	$329 \pm 84^{-d}$	
$D_0^*$	2357	$2369 \pm 22~^e$	280	$274 \pm 32$ $^e$	

 $<sup>^{</sup>a}$  The P-wave  $\cos^{7,9}$  was adjusted down 42 MeV.

Radiative transitions probe the internal structure of hadrons  $^{15,16,17}$ . Table 2 gives the quark model predictions for E1 radiative transitions between the 1P and 1S charm mesons  $^{10}$ . Some of these transitions should be observable. The  $D_1^0 \to D^{*0}\gamma$  and  $D_1^0 \to D^0\gamma$  transitions are of particular interest since the ratio of these partial widths are a measure of the  $^3P_1$   $^{-1}$   $P_1$  mixing angle in the charm meson sector and a good test of how well the HQL is satisfied.

The overall conclusion is that the quark model describes the P-wave charmed mesons quite well and models invoked to describe the  $D_{sJ}^*(2317)$  and  $D_{sJ}(2460)$  states must also explain their non-strange charmed meson partners.

Turning to the  $D_{sJ}$  states, the narrow j=3/2 states are identified with the  $D_{s1}(2536)$  and  $D_{s2}(2573)$  with their observed properties in good agreement with quark model predictions<sup>7,9</sup>. The j=1/2 states were predicted to be broad and to decay to DK and  $D^*K$  and were not previously observed. But the  $D_{sJ}^*(2317)$  is below DK threshold and the  $D_{sJ}(2460)$  is below  $D^*K$  threshold so the only allowed strong decay is  $D_{sJ}^{(*)} \to D_s^{(*)} \pi^0$  which violates isospin and is expected to have a small width<sup>15,16,17</sup>. As a consequence, the radiative transitions are expected to have large BR's and are an important diagnostic probe to understand the nature

<sup>&</sup>lt;sup>b</sup> Using the masses from column 2.

 $<sup>^</sup>e$  Average of the Belle  $^{11}$   $D_0^{*0}$  and FOCUS  $^{12}$   $D_0^{*0}$  and  $D_0^{*+}$  measurements.

Table 2. Partial widths and branching ratios for E1 transitions between 1Pand 1S charmed mesons. The widths are given in keV unless otherwise noted. The  $M_i$  and the total widths used to calculate the BR's are taken from Table 1. The matrix elements are calculated using the wavefunctions of Ref. 9.

Initial state	Final state	$M_i$ (GeV)	$M_f$ (GeV)	$k \pmod{MeV}$	$\langle 1P r nS\rangle$ (GeV <sup>-1</sup> )	Width (keV)	BR
$D_2^{*+}$	$D^{*+}\gamma$	2.459	2.010	408	2.367	57	0.25%
$D_2^{*0} \\ D_1^+$	$D^{*0}\gamma$	2.459	2.007	411	2.367	559	2.4%
$D_1^{\overline{+}}$	$D^{*+}\gamma$	2.422	2.010	377	2.367	8.8	$5 \times 10^{-4}$
1	$D^+\gamma$	2.422	1.869	490	2.028	58	0.3%
$D_1^0$	$D^{*0}\gamma$	2.422	2.007	380	2.367	87	0.5%
-	$D^0\gamma$	2.422	1.865	493	2.028	571	3.0%
$D_{1}^{\prime +}$	$D^{*+}\gamma$	2.428	2.010	382	2.367	37	$10^{-4}$
-	$D^+\gamma$	2.428	1.869	494	2.028	15	$4 \times 10^{-5}$
$D_{1}^{\prime 0}$	$D^{*0}\gamma$	2.428	2.007	385	2.367	369	0.1%
-	$D^0\gamma$	2.428	1.865	498	2.028	144	$4 \times 10^{-4}$
$D_{0}^{*+}$	$D^{*+}\gamma$	2.357	2.010	321	2.345	27	$10^{-4}$
$D_0^{*0}$	$D^{*0}\gamma$	2.357	2.007	324	2.345	270	0.1%

of these states 15,16,17. Although there are discrepancies between the quark model predictions and existing measurements they can be accommodated by the uncertainty in theoretical estimates of  $\Gamma(D_{sJ}^{(*)} \to D_s^{(*)} \pi^0)$  and by adjusting the  $^3P_1 - ^1P_1$  mixing angle for the  $D_{s1}$  states. As in the case of the  $D_1$  states, the radiative transitions to  $D_s$  and  $D_s^*$  can be used to constrain the  ${}^3P_1 - {}^1P_1$   $(c\bar{s})$  mixing angle.

The problem with the newly found  $D_{sJ}$  states are the mass predictions. Once the masses are fixed the narrow widths follow. My view is that the strong coupling to DK (and  $D^*K$ ) is the key to solving this puzzle.
